SUMMARY  Boolean functions with a few Walsh spectral values have important applications in sequence ciphers and coding theory. In this paper, we first construct a class of Boolean functions with at most five-valued Walsh spectra by using the secondary construction of Boolean functions, in particular, plateaued functions are included. Then, we construct three classes of Boolean functions with five-valued Walsh spectra using Kasami functions and investigate the Walsh spectrum distributions of the new functions. Finally, three classes of minimal linear codes with five-weights are obtained, which can be used to design secret sharing scheme with good access structures.

**key words:** Boolean function, bent function, plateaued function, Walsh transform, minimal linear codes

1. Introduction

Cryptographic functions are important components of cryptographic algorithms, and their cryptographic properties such as balance, nonlinearity, and differential uniformity are related to the security of cryptographic algorithms [1]–[3]. As the most important cryptographic functions, Boolean functions can be used in the design and analysis of symmetric cryptosystems. Some of these criteria can be characterized by the Walsh transform of Boolean functions, which is also a useful tool for studying Boolean functions. Bent functions introduced in [4] by Rothaus, are the maximally nonlinear Boolean functions. Plateaued functions [5] are generalization of bent functions. After that, in 2011 Tu et al. [6] characterized all Boolean functions with exactly two distinct Walsh transform values in terms of their spectrum. Recently, Jin et al. [7] presented three classes of Boolean functions with six-valued Walsh spectra and determined their Walsh spectrum distributions.

Linear codes have wide applications in consumer electronics, communication and data storage system. Besides, linear codes with a few weights have been used in secret sharing scheme [8], [9], authentication codes [10], association schemes [11], and strongly regular graphs [11]. A sufficient condition for judging whether a linear code is minimal was first presented by Ashikhmin and Barg [12], which is called the AB condition. In 2018, Ding et al. [13], [14] derived a necessary and sufficient condition for a linear code to be minimal. Meanwhile they presented some infinite families of minimal linear codes violating the AB condition.

The aim of this paper is to construct several classes of Boolean functions with at most five-valued Walsh spectra. More precisely, three classes of new Boolean functions with five-valued Walsh spectra are obtained, and we also investigate their Walsh spectrum distribution. As application, we construct three classes of minimal linear codes with five-weights, and the length, dimension and weight distribution of the codes are determined.

The rest of this paper is organized as follows. Section 2 introduces some notations and preliminary results on Boolean functions. Section 3 constructs a new class of Boolean functions with a few Walsh spectra are obtained, and we also investigate their Walsh spectrum distribution. As application, we construct three classes of minimal linear codes with five-valued Walsh spectra by using Kasami functions and determines their Walsh spectrum distributions. Meanwhile, three classes of minimal codes are derived from the new functions. Section 5 concludes the paper.

2. Preliminaries

In this section, we present some basic notations and facts on Boolean functions, Walsh transform, and minimal linear codes.

Let \( n \) be a positive integer. Let \( \mathbb{F}_2 \) be the finite field with \( 2^n \) elements and \( \mathbb{F}_2^* = \mathbb{F}_2 \setminus \{0\} \). An \( n \)-variable Boolean function is a mapping from finite field \( \mathbb{F}_2^n \) into \( \mathbb{F}_2 \). Denote by \( B_3 \) the set of Boolean functions from \( \mathbb{F}_{2^n} \) to \( \mathbb{F}_2 \).

Let \( r \) be a positive integer with \( r \mid n \). The trace function \( \text{Tr}_r(x) \) from \( \mathbb{F}_{2^n} \) to \( \mathbb{F}_2 \) is defined by

\[
\text{Tr}_r(x) = x + x^{2r} + \cdots + x^{2^{n-r-1}},
\]

where \( x \in \mathbb{F}_{2^n} \).
Let $\mathbb{F}_2^n$ be the $n$-dimensional vector space over the finite field $\mathbb{F}_2$. There is a one-to-one correspondence between $\mathbb{F}_2^n$ and $\mathbb{F}_2^m$ since every $a \in \mathbb{F}_2^m$ can be represented uniquely by $a = a_1a_2a_3 + \ldots + a_na_n$, where $a_1, a_2, a_3, \ldots, a_n$ is a basis of $\mathbb{F}_2^n$ over $\mathbb{F}_2$.

The Walsh transform of $f \in \mathcal{B}_n$ calculates the correlations between this function and the linear functions, which is defined by

$$
\hat{f}(a) = \sum_{x \in \mathbb{F}_2^n} (-1)^{f(x) \oplus Tr_i^*(ax)}, \quad a \in \mathbb{F}_2^m.
$$

(1)

If $\hat{f}$ has only $t$ different values, then we say $f$ has $t$-valued Walsh spectrum. Let

$$N_i = |\{a \in \mathbb{F}_2^n : \hat{f}(a) = v_i\}|, 1 \leq i \leq t,$

where $|S|$ denotes the cardinality of a set $S$. Then we have the following system of equations

$$
\begin{align*}
\sum_{i=1}^{t} N_i &= 2^n, \\
\sum_{i=1}^{t} N_i v_i &= 2^n(-1)^{t-1}, \\
\sum_{i=1}^{t} N_i v_i^2 &= 2^{2n}.
\end{align*}
$$

(2)

The bivariate representation of a Boolean function $f(x)$ over $\mathbb{F}_2^n$ is based on the identification $\mathbb{F}_2^n \cong \mathbb{F}_2^m \times \mathbb{F}_2^m$ for $n = m + k$. For the bivariate trace representation over $\mathbb{F}_2^m \times \mathbb{F}_2^m$, the Walsh transform of $f(y,z)$ at any $(a_1,a_2) \in \mathbb{F}_2^m \times \mathbb{F}_2^m$ is

$$
\hat{f}(a_1,a_2) = \sum_{y \in \mathbb{F}_2^m, z \in \mathbb{F}_2^m} (-1)^{f(y,z) + Tr_i^*(a_1y) + Tr_j^*(a_2z)}.
$$

(3)

Definition 1: [16] Let $f \in \mathcal{B}_n$ with $n = 2m$ and $m$ be a positive integer. If for any $a \in \mathbb{F}_2^m$, $\hat{f}(a) = \pm 2^m$, then $f(x)$ is called bent function.

If $f(x)$ is bent, then its dual function $\tilde{f}$ is also bent and the relation between them is as follows:

$$
f(x) = 2^m(-1)^{\tilde{f}(x)}.
$$

For even $n$, a function $f \in \mathcal{B}_n$ is said to be semi-bent if $\hat{f}(\omega) \in \{0, \pm 2^{n/2}\}$ for all $\omega \in \mathbb{F}_2^n$. For odd $n$, a function $f \in \mathcal{B}_n$ is said to be semi-bent if $\hat{f}(\omega) \in \{0, \pm 2^{n/2} + 1\}$ for all $\omega \in \mathbb{F}_2^n$. A function $f \in \mathcal{B}_n$ is said to be $r$th-planeated if $\hat{f}(\omega) \in \{0, 2^{n/2-r}\}$. Obviously, bent function is $n$th-planeated and semi-bent is $(n-2)$th-planeated when $n$ is even.

Lemma 1: [17] Let $n = 2m$ and $\lambda \in \mathbb{F}_2^n$. Then $f(x) = Tr_1^\lambda(ax^{2^m+1})$ is a bent function, and satisfies

$$
\hat{f}(a) = 2^m(-1)^{Tr_1^\lambda(ax^{2^{m+1}})+1}, \quad a \in \mathbb{F}_2^m.
$$

Lemma 2: [17] Let $n = 2m$ and $\lambda \in \mathbb{F}_2^n$. Let $(a,b) \in \mathbb{F}_2^m \times \mathbb{F}_2^m$ such that $a \neq b$ and $Tr_1^\lambda(ax^{2^m+1}) = 0$. Then $h(x) = Tr_1^\lambda(ax^{2^m+1}) + Tr_1^\lambda(by^{2^m+1})$ is bent and its dual $h^*$ is given by

$$
h^*(x) = \prod_{r \in [a,b]} (Tr_1^\lambda(ax^{2^m+1}) + Tr_1^\lambda(by^{2^m+1})) + Tr_1^\lambda(ax^{2^m+1}) + 1.
$$

(3)

3. The Construction of New Boolean Functions with a Few Walsh Spectral Values

In this section, we will construct a new class of Boolean functions with a few Walsh spectral values.

Let $b(x) = g(x) + g(x)$, $g(x)$, $g(x) \in \mathcal{B}_n$. For any integer $n, k \geq 2$, we define

$$
f(x, y) = g(x) + Tr_1^\lambda(c_1y)Tr_1^\lambda(c_2y)g(x),
$$

(4)

where $c_1, c_2 \in \mathbb{F}_2^m$ and $c_1 \neq c_2$.

Now we present the main results of the paper.

Theorem 1: For any $(u, v) \in \mathbb{F}_2^n \times \mathbb{F}_2^n$, the Walsh transform of $f(x, y)$ in Eq. (4) satisfies

$$
\hat{f}(u, v) = \begin{cases} 2^{k-2}(\bar{g}(u) + \bar{g}(v)), & v = 0, \\
2^{k-2}(g(u) - \bar{g}(u)), & v \in \{c_1, c_2\}, \\
-2^{k-2}(g(u) - \bar{g}(u)), & v = c_1 + c_2, \\
0, & \text{otherwise.}
\end{cases}
$$

(5)

Proof: For any $(\epsilon_1, \epsilon_2) \in \mathbb{F}_2^2$, we define the sets

$$
T(\epsilon_1, \epsilon_2) = \{y \in \mathbb{F}_2^n : \hat{T}^\lambda_1(c_1y) = \epsilon_1, \hat{T}^\lambda_1(c_2y) = \epsilon_2\}.
$$

It is easy to see that $H = T(0, 0)$ is a subspace of $\mathbb{F}_2^n$ with $dim(H) = k - 2$, and $H^\perp = \{y \in \mathbb{F}_2^n : \forall x \in H, \hat{T}^\lambda_1(xy) = 0\} = \{0, c_1, c_2, c_1 + c_2\}$. Then there exists $\alpha = (\epsilon_1, \epsilon_2) \in T(\epsilon_1, \epsilon_2)$ such that $\mathbb{F}_2^n = \bigcup_{\epsilon_1, \epsilon_2 \in \mathbb{F}_2} T(\epsilon_1, \epsilon_2) + H$ for any $(\epsilon_1, \epsilon_2) \in \mathbb{F}_2^2$. Then for any $(u, v) \in \mathbb{F}_2^n \times \mathbb{F}_2^n$, we have

$$
\hat{f}(u, v) = \sum_{x \in \mathbb{F}_2^n, \hat{g}(x) \in H^\perp} (-1)^{f(x, y) + \hat{T}^\lambda_1(\epsilon_2y) + \hat{T}^\lambda_1(\epsilon_1y)}
$$

$$
= \sum_{x \in \mathbb{F}_2^n, \hat{g}(x) \in H^\perp} (-1)^f + \hat{T}^\lambda_1(\epsilon_2y) + \hat{T}^\lambda_1(\epsilon_1y)
$$

$$
= \sum_{x \in \mathbb{F}_2^n, \hat{g}(x) \in H^\perp} \left( (-1)^f \sum_{\alpha \in \mathbb{F}_2^2} \right) (-1)^{\hat{T}^\lambda_1(ax^{2^m+1}) + \hat{T}^\lambda_1(by^{2^m+1})}
$$

$$
= \hat{g}(u) - \hat{g}(u)
$$

$$
= \hat{b}(u) \in \mathbb{F}_2^n
$$

$$
= 0
$$

Thus, we complete the proof.

(6)

Corollary 1: Let $g(x)$ be bent, and $g(x) = 1$. Then $f(x, y)$ in Eq. (4) is $(k-2)$th-planeated, and $f(u, v) \in \{0, \pm 2^{k-2}\}$. In particular, if $k = 2$, then $f(x, y)$ is bent, and if $k = 3$ or $4$, then $f(x, y)$ is semi-bent.
4. Construction of the Five-Valued Walsh Spectra Boolean Function and Its Application

In this section, based on the functions in Sect. 3, we will construct three classes five-valued Walsh spectra Boolean functions by using Kasami function and determine the Walsh spectrum distributions, then investigate the applications in linear codes.

Below, we always put $n = 2m > 4$, $g(x) = \text{Tr}_q^m(\lambda x^{2n+1})$, where $\lambda \in \mathbb{F}_{2^n}$. We introduce the following notations for clarity.

$$ A = \text{Tr}_q^m(\lambda^{-1} u^{2n+1}), \text{ for any } u \in \mathbb{F}_{2^n}, $$

$$ N_j = | \{(u, v) \in \mathbb{F}_{2^n} \times \mathbb{F}_{2^n} : \widehat{f}(u, v) = 0 \}|, $$

$$ N_{2+i} = | \{(u, v) \in \mathbb{F}_{2^n} \times \mathbb{F}_{2^n} : \widehat{f}(u, v) = (-1)^{2^{i+1} + k} \}|, $$

$$ N_{4+i} = | \{(u, v) \in \mathbb{F}_{2^n} \times \mathbb{F}_{2^n} : \widehat{f}(u, v) = (-1)^{i+1} \alpha \hat{x}^{2^{i+1}} \}|, $$

where $i \in \{0, 1\}$.

According to Lemma 1, it is easy to get

$$ \sum_{u \in \mathbb{F}_{2^n}} (-1)^A = 2^2(-1)^{\text{Tr}_q^m(\lambda^{2n+1})} = -2^2. $$

(7)

4.1 The Spectrum Distributions for $g(x) = \text{Tr}_q^m(x^{2n+1})$

In this subsection, let $g(x) = \text{Tr}_q^m(x^{2n+1})$, $r \in \mathbb{F}_{2^n}$ in Eq. (4). Then

$$ f(x, y) = \text{Tr}_q^m(c_1 y)\text{Tr}_q^m(c_2 y)\text{Tr}_q^m(x^{2n+1}) + \text{Tr}_q^m(\lambda x^{2n+1}), $$

(8)

where $\lambda \neq r$, $c_1, c_2 \in \mathbb{F}_{2^n}$ and $c_1 \neq c_2$.

For this function we have the following lemma which will be used in the sequel.

**Lemma 3:** For any $(u, v) \in \mathbb{F}_{2^n} \times \mathbb{F}_{2^n}$, the Walsh transform of $\hat{f}(x, y)$ in Eq. (8) is as following

$$ \hat{f}(u, v) = \begin{cases} -2^{2+k-2}(3(-1)^A + (-1)^{B}), & v = 0, \\ -2^{2+k-2}((-1)^{A} - (-1)^{B}), & v \in \{c_1, c_2\}, \\ 2^{2+k-2}((-1)^{A} - (-1)^{B}), & v = c_1 + c_2, \\ 0, & \text{otherwise}. \end{cases} $$

(9)

where $B = \text{Tr}_q^m((r + \lambda^{-1}) u^{2n+1})$.

**Theorem 2:** With the notations above. The Walsh spectrum distribution of $f(x, y)$ in Eq. (8) satisfies

$$ \hat{f}(u, v) = \begin{cases} 0, & 2^{n+k} - 5 \cdot 2^{n-1} - 3 \cdot 2^{2-1} \text{ times}, \\ -2^{2+k}, & 2^{n-2} - 3 \cdot 2^{2-2} \text{ times}, \\ 2^{2+k}, & 2^{n-2} + 2 \cdot 2^{2-2} \text{ times}, \\ \pm 2^{2+k-1}, & 2^n + 2 \cdot 2^2 \text{ times}. \end{cases} $$

(10)

**Proof:** By Lemma 3, we discuss the Walsh transform of function $\hat{f}(x, y)$ in two cases:

1. If $A = B$, then

$$ \hat{f}(u, v) = \begin{cases} (-1)^{A+1} \cdot 2^{2+k}, & v = 0, \\ 0, & \text{otherwise}. \end{cases} $$

2. If $A \neq B$, then

$$ \hat{f}(u, v) = \begin{cases} (-1)^{A+1} \cdot 2^{2+k-1}, & v \in \{c_1, c_2\}, \\ (-1)^{A} \cdot 2^{2+k-1}, & v = c_1 + c_2, \\ 0, & \text{otherwise}. \end{cases} $$

Now we discuss the Walsh spectrum distribution of $f(x, y)$. We first consider $N_4$, the number of $(u, v) \in \mathbb{F}_{2^n} \times \mathbb{F}_{2^n}$ such that $\hat{f}(u, v) = -2^2 + 2^2$, and this will happen if $v = 0$ and $A = B = 0$. So we have

$$ N_4 = \frac{1}{2^2} \sum_{u \in \mathbb{F}_{2^n}} (1 + (-1)^A)(1 + (-1)^B). $$

Since it follows from Lemma 1 and Eq. (7) that $\sum_{u \in \mathbb{F}_{2^n}} (-1)^B = \sum_{u \in \mathbb{F}_{2^n}} (-1)^{A+B} = -2^2$, we can get

$$ N_4 = \frac{1}{2^2}(2^n - 2^2 - 2^2 - 2^2) = 2^{n-2} - 3 \cdot 2^{2-2}. $$

Next, we will calculate $N_5$, which corresponding to $v = 0$ and $A = B = 1$. Then

$$ N_5 = \frac{1}{2^2} \sum_{u \in \mathbb{F}_{2^n}} (1 + (-1)^A)(1 - (-1)^B) $$

$$ = 2^{n-2} + 2^2 - 2^2. $$

Since $\hat{f}(0, 0) = 0$, then by applying the value of $N_4$ and $N_5$ to Eq. (2), and solving the system of linear equations yields that

$$ \begin{cases} N_1 = 2^{n+k} - 5 \cdot 2^{n-1} - 3 \cdot 2^{2-1}, \\ N_2 = N_3 = 2^n + 2^n. \end{cases} $$

Therefore, we have completed the proof. □

**Example 1:** Let $n = 8$, $k = 2$, and $\zeta$ be a primitive element in $\mathbb{F}_{2^8}$ such that $\zeta^8 + \zeta^6 + \zeta^5 + \zeta + 1 = 0$. Let $c_1 = 1, c_2 = \zeta^6$, $\lambda = \zeta^{17}, r = \zeta^{34}$. It was verified by a Magma program that

$$ f(x, y) = \text{Tr}_q^m(\lambda x^{17}) + \text{Tr}_q^m(c_1 y)\text{Tr}_q^m(c_2 y)\text{Tr}_q^m(x^{17}) $$

has the Walsh spectrum distribution as following

$$ \hat{f}(u, v) = \begin{cases} 0, & 2^{10} - 83 \cdot 2^3 \text{ times}, \\ -2^6, & 2^6 - 3 \cdot 2^5 \text{ times}, \\ 2^6, & 2^6 + 2^5 \text{ times}, \\ \pm 2^5, & 2^8 + 2^4 \text{ times}. \end{cases} $$

which is consistent with Theorem 2.

4.2 The Spectrum Distributions for $g(x) = \text{Tr}_q^m(ax)$

In this subsection, let $g(x) = \text{Tr}_q^m(ax)$ in Eq. (4). Then

$$ f(x, y) = \text{Tr}_q^m(c_1 y)\text{Tr}_q^m(c_2 y)\text{Tr}_q^m(ax) + \text{Tr}_q^m(\lambda x^{2n+1}), $$

(11)
where \( a \in \mathbb{F}_{2^n}^*, c_1, c_2 \in \mathbb{F}_{2^n}^* \) and \( c_1 \neq c_2 \).

By Theorem 1, the following lemma is obtained.

**Lemma 4:** For any \((u, v) \in \mathbb{F}_{2^n} \times \mathbb{F}_{2^n}\), the Walsh transform of \( f(x, y) \) in Eq. (11) is as following

\[
\hat{f}(u, v) = \begin{cases} 
-2^{k-2}((1)^4 - (1)^3), & v = 0, \\
2^{k-2}((1)^4 - (1)^3), & v \in \{c_1, c_2\}, \\
2^{k+2}((1)^4 - (1)^5), & v = c_1 + c_2, \\
0, & \text{otherwise}.
\end{cases}
\]

where \( B = \text{Tr}_1^n(\lambda^{-1}(u + a)2^{n+1}) \).

**Theorem 3:** The Walsh spectrum distribution of \( f(x, y) \) in Eq. (11) is as following

\[
\hat{f}(u, v) = \begin{cases} 
0, & 2^{n+k} - 5 \cdot 2^{n-1} \text{ times}, \\
\pm 2^{k+1}, & 2^{n-2} \pm 2^{n-1} \text{ times}, \\
\pm 2^{k+1}, & \text{2 times}.
\end{cases}
\]  

**(Proof):** The proof is similar to that of Theorem 2, so we only give a sketch. By Lemma 4, for any \((u, v) \in \mathbb{F}_{2^n} \times \mathbb{F}_{2^n}\), we have

\[
\hat{f}(u, v) = \begin{cases} 
(-1)^{k+1}2^{k+2}A, & A = B, v = 0, \\
(-1)^{k+1}2^{k+2}B, & A \neq B, v \in \{0, c_1, c_2\}, \\
(-1)^{k+1}2^{k+1}, & A \neq B, v = c_1 + c_2, \\
0, & \text{otherwise}.
\end{cases}
\]

Now we discuss the Walsh spectrum distribution of \( f(x, y) \). We first consider \( N_4 \), the number of \((u, v) \in \mathbb{F}_{2^n} \times \mathbb{F}_{2^n}\) such that \( \hat{f}(u, v) = -2^{k+1} \). It follows from the equation above and Lemma 1 that

\[
N_4 = \frac{1}{2^2} \sum_{u \in \mathbb{F}_{2^n}} \sum (1 + (-1)^4)(1 + (-1)^9)
= \frac{1}{2^2} \sum_{u \in \mathbb{F}_{2^n}} (1 + (-1)^4 + (-1)^9 + (-1)^{4+B})
= \frac{1}{2^2}(2^n - 2^2 - 2^2 - 0)
= 2^{n-2} - 2^{n+1}.
\]

Next, we examine \( N_5 \), which correspond to the case of \( v = 0 \) and \( A = B = 1 \). Then with the similar calculation of \( N_4 \), we get

\[
N_5 = 2^{n-2} + 2^{n+1}.
\]

Using the same argument as in the proof of Theorem 2, we obtain

\[
\begin{align*}
N_1 &= 2^{n+k} - 5 \cdot 2^{n-1}, \\
N_2 &= N_3 = 2^n.
\end{align*}
\]

Therefore, the spectrum distribution of \( f(x, y) \) is

\[
\hat{f}(u, v) = \begin{cases} 
0, & 2^{n+k} - 5 \cdot 2^{n-1} \text{ times}, \\
\pm 2^{k+1}, & 2^{n-2} \pm 2^{n-1} \text{ times}, \\
\pm 2^{k+1}, & \text{2 times}.
\end{cases}
\]

This completes the proof.

**Example 2:** Let \( n = 8, k = 2 \), and \( \zeta \) be a primitive element in \( \mathbb{F}_2^8 \) such that \( \zeta^8 + \zeta^6 + \zeta^3 + \zeta + 1 = 0 \). Let \( c_1 = 1, c_2 = \zeta^8, \lambda = \zeta^7, a = \zeta^2 \). It was verified by a Magma program that

\[
f(x, y) = \text{Tr}_3^n(\lambda x^7) + \text{Tr}_2^n(c_1 y)\text{Tr}_1^n(c_2 y)\text{Tr}_1^n(ax)
\]

has the Walsh spectrum distribution as follows

\[
\hat{f}(u, v) = \begin{cases} 
0, & 2^{10} - 5 \cdot 2^7 \text{ times}, \\
\pm 2^5, & 2^6 \pm 2^3 \text{ times}, \\
\pm 2^5, & 2^6 \text{ times}.
\end{cases}
\]

This is consistent with Theorem 3.

4.3 The Spectrum Distributions for \( g(x) = \text{Tr}_1^n(ax)\text{Tr}_1^n(bx) \)

In this subsection, let \( g(x) = \text{Tr}_1^n(ax)\text{Tr}_1^n(bx), (a, b) \in \mathbb{F}_{2^n} \times \mathbb{F}_{2^n} \) such that \( a \neq b \) in Eq. (4). Then

\[
f(x, y) = \text{Tr}_1^n(c_1 y)\text{Tr}_1^n(c_2 y)\text{Tr}_1^n(ax)\text{Tr}_1^n(bx) 
+ \text{Tr}_1^n(\lambda x^{2^n-1}),
\]

where \( r \in \mathbb{F}_{2^n} \), and \( \text{Tr}_1^n(\lambda x^{2^n-1}) = 0, c_1, c_2 \in \mathbb{F}_{2^n} \) and \( c_1 \neq c_2 \).

By Theorem 1, we have the following result.

**Lemma 5:** Let \( f(x, y) \) be defined as in Eq. (13). For any \((u, v) \in \mathbb{F}_{2^n} \times \mathbb{F}_{2^n}, \) the Walsh transform of \( f(x, y) \) is as following

\[
\hat{f}(u, v) = \begin{cases} 
0, & 2^{n+k} - 7 \cdot 2^{n-2} \text{ times}, \\
\pm 2^{k+1}, & 3 \cdot 2^{n-3} \pm 2^{n-1} \text{ times}, \\
\pm 2^{k+1}, & 2^{n+1} \text{ times}.
\end{cases}
\]

**(Proof):** The proof is similar to that of Theorem 2, so we give a brief proof. By Lemma 5, for any \((u, v) \in \mathbb{F}_{2^n} \times \mathbb{F}_{2^n}, \) we have

\[
\hat{f}(u, v) = \begin{cases} 
(-1)^{k+1}2^{k+2}A, & \Gamma = 0, v = 0, \\
(-1)^{k+1}2^{k+2}B, & \Gamma = 1, v \in \{0, c_1, c_2\}, \\
(-1)^{k+1}2^{k+1}, & \Gamma = 1, v = c_1 + c_2, \\
0, & \text{otherwise}.
\end{cases}
\]

Now we discuss the Walsh spectrum distribution of \( f(x, y) \). Let

\[
\Gamma_0 = \text{Tr}_1^n(\lambda^{-1}a^{2^n+1}) + \text{Tr}_1^n(\lambda^{-1}a^{2^n}) \text{,} \quad \\
\Gamma_1 = \text{Tr}_1^n(\lambda^{-1}b^{2^n+1}) + \text{Tr}_1^n(\lambda^{-1}b^{2^n}).
\]
First, considering $N_4$, the number of $(u, v) \in \mathbb{F}_2 \times \mathbb{F}_2$ such that $\tilde{f}(u, v) = -2^{s+k}$, which correspond to $v = 0$ and $A = \Gamma = 0$. It is obvious that $(\Gamma_0, \Gamma_1) \in \{(0, 0), (0, 1), (1, 0)\}$ when $\Gamma = 0$. Let $N_{ij}$ be the number of $(u, v) \in \mathbb{F}_2 \times \mathbb{F}_2$ such that $\tilde{f}(u, v) = -2^{s+k}$ when $(\Gamma_0, \Gamma_1) = (j_0, j_1)$, where $0 \leq j \leq 2$ and $j = 2j_0 + j_1$. Then

$$N_4 = N_{40} + N_{41} + N_{42}.$$

Next, we calculate $N_{40}, N_{41}, N_{42}$.

$$N_{40} = \frac{1}{2^3} \sum_{u \in \mathbb{F}_2} (1 + (-1)^{A})(1 + (-1)^{F_0})(1 + (-1)^{F_1}) = \frac{1}{2^3} \sum_{u \in \mathbb{F}_2} (1 + (-1)^{F_0} + (-1)^{F_1}$$

$$+(-1)^A + (-1)^{A+T_0} + (-1)^{T_0+T_1}$$

$$+(-1)^{A+T_1} + (-1)^{A+T_0+T_1}).$$

Due to the definition of $\Gamma_0, \Gamma_1$ and $a \neq b$, we can get

$$\sum_{u \in \mathbb{F}_2} (-1)^{F_0} = \sum_{u \in \mathbb{F}_2} (-1)^{F_1} = \sum_{u \in \mathbb{F}_2} (-1)^{T_0+T_1} = 0.$$

By Lemma 1, we have $\sum_{u \in \mathbb{F}_2} (-1)^{A+T_i} = -2^{\frac{i}{2}}, i = 0, 1. 1.$

Notice that $Tr(f(\lambda^{-1}b^2a)) = 0$. For convenience, let $A_0 = Tr(f(\lambda^{-1}a^2b^{s+1}))$. Then

$$\sum_{u \in \mathbb{F}_2} (-1)^{A+T_0+T_1} = \sum_{u \in \mathbb{F}_2} (-1)^{T_0(\lambda^{-1}a^{2^{s+1}})}$$

$$-(-1)^{Tr(\lambda^{-1}(a+b)^{s+1}a+A_0+a_0)}$$

$$= (-1)^{A_0+a_0}2^{\frac{1}{2}}(-1)^{Tr(k(\lambda^{-1}(a+b)^{s+1})^{s+1}+1}$$

$$= 2^{\frac{3}{2}}(-1)^{2(A_0+a_0)+1}$$

$$= -2^{\frac{3}{2}}.$$

Taking the above results into Eq. (14) yields

$$N_{40} = 2^{n-3} - 2^{\frac{n}{2}-1}.$$
(2) where \( A_1 = 5 \cdot 2^{n-1} + 2^{n+k-1} - 1 \), \( A_2 = 2^{n-2} - 2^{n-1} \), \( A_3 = 2^{n-1} + 2^{n+k-1} - 1 \), \( A_4 = 2^n \), if \( f(x, y) \) is defined by Eq. (11).

(3) where \( A_1' = -7 \cdot 2^{n-3} + 2^{n+k+1} - 1 \), \( A_2' = 3 \cdot 2^{n-3} - 2^{n-1} \), \( A_3' = 3 \cdot 2^{n-3} + 2^{n-1} \), \( A_4 = 2^{n-1} \), if \( f(x, y) \) is defined by Eq. (13).

**Proof:** According to Theorems 2–4 and Lemma 7, we have the weight distribution of \( \mathcal{C}_f \) is in Table 1. Obviously, \( w_{\min} / w_{\max} > 1/2 \). Thus, \( \mathcal{C}_f \) satisfies AB condition according to Lemma 6, that is, \( \mathcal{C}_f \) is narrow minimal. \( \square \)

5. Conclusion

In this paper, a family of Boolean functions with a few Walsh spectrum was promoted. Moreover, we constructed three classes of Boolean functions with five-valued Walsh spectra and investigated the distributions of Walsh spectrum. As application, three classes of minimal linear codes with five-weights were obtained from the new functions, and the length, dimension and weight distribution were determined. The results show that the new codes are all minimal and thus they can be used to design the secret sharing scheme with sound access structures.
